The lichen genus *Lecidella* (Lecanoraceae), with special reference to the Tasmanian species

Gintaras Kantvilas¹ and John A. Elix²

¹Tasmanian Herbarium, Private Bag 4, Hobart, Tasmania 7001, Australia (corresponding author)

Introduction

In continuing our review of *Lecidea*-like crustose lichens in temperate Australia (e.g. Kantvilas & Elix 1994, 2007; Kantvilas *et al.* 1999, 2005; Kantvilas 2001, 2008a, 2008b, 2009, 2011; Kantvilas & La Greca 2008), we have turned our attention to the genus *Lecidella* Körb. This genus of approximately 50 species (Kirk *et al.* 2001) is well represented in all major regions of the world including Antarctica (Øvstedal & Lewis Smith 2001). It occurs mostly in cold or cool temperate climates where it colonises rocks, bark, wood and soil, as well as man-made substrata such as concrete; several species are particularly adapted to eutrophicated habitats.

Although *Lecidella* has not been the subject of a comprehensive revision in Australia, four species were treated by Rambold (1989) in his account of mainland Australian lecideoid lichens. Australian taxa and collections have also been studied in the course of a series of papers by J.-G. Knoph and co-workers, who greatly advanced the chemotaxonomic knowledge of the genus (Knoph 1990; Knoph *et al.* 1999; Knoph & Leuckert 2000). Miscellaneous reports of species from Australia, including new state records, have also been added by Allen *et al.* (2001), Elix (2006, 2008, 2010), Elix and Kantvilas (1995), Hertel (1985, 1989, 1990) and Kantvilas *et al.* (2008). In his checklist of Australian lichens, McCarthy (2012) records eight species for Australia, of which four occur in Tasmania. Meanwhile, Galloway (2007) treats nine species for New Zealand and provides a good overview of the genus, which is of particular relevance to the Australasian region.

The present study is essentially Tasmanian in focus, although we have also studied many additional collections from elsewhere in southern Australia in order to provide a context for our work. We recognise eight species, of which three are described as new, and transfer to *Lecidella* a further taxon previously included within *Lecidea*.

Abstract

Eight species of Lecidello (Lecanoraceae, lichenised Ascomycetes) are recorded for Tasmania: L. destituta Kantvilas & Elix sp. nov., L. elaeochromo (Ach.) Hazsl., L. flavovirens Kantvilas & Elix sp. nov., L. granulosula (Nyl.) Knoph & Leuckert, L. stigmatea (Ach.) Hertel & Leuckert, L. sublapicida (C. Knight) Hertel and L. xylogena (Müll. Arg.) Kantvilas & Elix comb. nov. (all present in mainland Australia), and the Tasmanian endemic L. montono Kantvilas & Elix sp. nov. All species are described in full, and notes on their characterisation, inter-relationships, distribution and ecology are provided. The status of the names Lecidea minutula Müll. Arg. and L. leptolomoides Müll. Arg., based on collections from Victoria, is discussed briefly.

Key words: blodiversity, *Lecideo*, lichenised Ascomycetes, temperate Australia

Muellerio 31:31-47 (2013)

Materials and methods

The study is based chiefly on collections by the authors, housed mainly in the Tasmanian Herbarium (HO) and on selected collections from other herbaria as cited in the text. Diagnostic characters of non-Tasmanian species, studied for comparative purposes, were determined from reference herbarium material (mainly from HO), and from published descriptions.

Descriptions are based on hand-cut sections of the thallus and ascomata, examined with high-power light microscopy. Mounting media included water, 15% KOH (K), Lugols lodine after pretreatment with K, Lactophenol Cotton Blue after pretreatment with K and washing with water, and 50% HNO₃ (N). Dimensions of asci and ascospores are based on 25 and 60–100 observations respectively. The latter are presented in the format: 5th percentile–mean–95th percentile; outlying extreme values are given in parentheses. Routine chemical analyses using thin-layer chromatography follow standard methods (Orange et al. 2001). Critical extracts of a representative selection of specimens of each taxon were analysed using high-performance liquid chromatography (Elix et al. 2003).

Characteristics of the genus and species

Lecidella is characterised by: a crustose thallus containing a trebouxioid photobiont with ± globose cells 6-18 μm diam.; biatorine apothecia that are typically a shade of brown or black and include blue-green, N+ crimson pigments [essentially cinereorufa green of Meyer and Printzen (2000)]; a persistent, typically annular proper excipulum composed of radiating, thick-walled hyphae c. 3-5 µm thick that become expanded to c. 5-10 µm and increasingly paraplectenchymatous and internally pigmented towards the outer edge; clavate, eight-spored asci with the outer wall amyloid, a well-developed, intensely amyloid tholus, almost but not completely penetrated by a weakly amyloid, ± conical masse axiale with a rounded apex, and a poorly developed ocular chamber; mostly simple paraphyses that usually separate readily in KOH; and simple, hyaline, non-halonate ascospores with a distinct, thin, singlelayered wall when mature. In the literature, the asci are mostly referred to as 'Lecanora-type' although they are more accurately described as Lecidella-type, as

illustrated by Hafellner (1984). In Lecanora, the asci differ subtly by having the tholus penetrated entirely by the cylindrical to barrel-shaped masse axiale. Chemistry of the genus is variable and very frequently includes a suite of xanthones.

At generic rank, Lecidella is usually not difficult to recognise, although there are some superficially similar genera, including Carbonea (Hertel) Hertel, Japewiella Printzen, Mycoblastus Norman, Megalaria Hafellner, Tasmidella Kantvilas, Hafellner & Elix and Ramboldia Kantvilas & Elix, with which it has some features in common. Salient features of these taxa are summarised in Table 1. In the course of the present study, we found that the genus most likely to be confused with Lecidella was Japewiella, which has ± identical asci, a lax hymenium and, frequently, a xanthone-dominated thallus chemistry. The main difference between the two genera is that the excipulum of Japewiella consists of a loose reticulum of radiating, branched and an astomosing hyphae c. 1 µm thick in a gelatinous matrix (Printzen 1999; Kantvilas 2011). Several undescribed species of Japewiella were recognised during the present work and await study in the future.

Thallus morphology and chemistry, apothecial pigmentation and ascospore dimensions are the chief characters by which species of Lecidella are circumscribed. Chemistry is particularly critical, complicated by the fact that identification of the many xanthones present, as well as distinguishing such key compounds as vicanicin and diploicin, is difficult and essentially requires high-performance liquid chromatography. Determination of the chemistry of each specimen was an essential aspect of this study. Yet, having circumscribed the species, it was found that each can usually be identified without difficulty using morphological and anatomical characters, and so distinguishing the different species is not necessarily limited to the practitioner with access to specialist laboratory equipment.

Taxonomy

1. Lecidella destituta Kantvilas & Elix, sp. nov.

MycoBank No.: MB803599

Lecidellae elaeochromae aemulans sed atranorinum solum continenti et hymenio guttis olei crystalisque insperso differt.

Table 1. Comparison of salient features of Lecidella and superficially similar genera (based on observation of selected specimens and literature)

		sar gulnarius graup)1	dissimulans graup	lat. 23.4	nusmingin	vamoonia	napewiena	Caroanea
excipulum	persis ent, composed of radiating, thick-walled hyphae that become parap-ectentchymatous and internally pigmented at the outer edge	reduced, soon excluded, composed of short-celled, reticulate hyphae	reduced, soon excluded, composed of branched and anastomosing hyphae similar to paraphyses	persistent, two-layered, composed of branched and anastomosing, radiating	persistent, composed of branched and anastomosing, radiating hyphae	typically reduced and soon excluded, composed of branched and anastomosing, radiating hyphae	persistent, composed of branched and anastomosing hyphae	persistent to excluded, typically opaque and carbonised

⁹ Spribille & Printzen (2007); ¹⁰ Kantvilas (2011); ¹¹ Chambers et al. (2009); ¹² Knoph et al. (2004)

Type: **NEW SOUTH WALES.** Gillenbah State Forest, 8 km S of Narrandera, 34°47′51″S 146°30′00″E, 170 m alt., on *Callitris* in mallee scrub, 16 April 2009, *J.A. Elix 39928* (holotype: HO; isotype: CANB).

Thallus typically areolate, deeply cracked, rather lumpy and uneven, more rarely very thin, effuse and revealing a blue-black prothallus beneath, pale pinkish brown, grey-brown to whitish grey, undelimited, esorediate, forming irregular patches c. 1-5 cm wide. Apothecia 0.2-0.9 mm wide, sessile, basally constricted; disc mostly persistently plane, sometimes becoming undulate but only rarely convex, black, matt, epruinose. Proper excipulum black, matt to glossy, persistent, entire, in section 20-40 µm thick, ± opaque brown within, unchanged in K, N+ intensifying orange-brown, also with additional blue-green, N+ crimson pigment, especially at the upper and outer edges. Hypothecium 40-90 µm thick, pale yellow-brown to yellow-orange, intensifying yellow-orange in K and N. Hymenium 60-90 µm thick, separating easily in K, not overlain by epihymenial granules but densely inspersed, especially towards the base, with minute, colourless crystals and oil droplets that do not dissolve in K, in the upper part intensely greenish blue, K ± grey-green, N+ crimson, towards the base mostly colourless, often K± very faint pinkish. Asci 45-60 \times 14-22 μ m. Paraphyses 1.5-2.5 μ m thick, simple; apices usually expanded to 2-4.5 µm thick, mostly with an external, blue-green, N+ crimson cap but sometimes unpigmented. Ascospores broadly ellipsoid, occasionally slightly bent, $11-13.7-16(-17) \times (5.5-)6-$ 7.2-9 µm. Conidiomata not observed. Fig. 1A

Chemical composition: atranorin , ±chloroatranorin; thallus K± yellowish, P-, KC-, C-, UV-.

Remarks: This species is characterised chiefly by the combination of the thallus containing atranorin only, and by the conspicuously inspersed hymenium. In other respects, such as disposition of pigments and the yellow-brown hypothecium, it is very similar to Lecidella elaeochroma. Additional, more subtle characters that distinguish L. destituta from L. elaeochroma include the apothecia, which generally do not become markedly convex with an excluded exciple, and the lack of brownish epihymenial granules; the ecology of the two taxa (see below) is also starkly different. Although the ascospores of L. destituta fall within the size range

of *L. elaeochroma*, they are nevertheless slightly longer and broader (as demonstrated by mean values). It is probably due to the lack of epihymenial granules that the blue-green apothecial pigment in *L. destituta* often appears relatively bright. The characteristic inspersion of the hymenium is most pronounced in New South Wales and South Australian specimens, whereas in Tasmanian material, this is mostly restricted to the base of the hymenium. The crystals and droplets do not fluoresce in polarised light, nor dissolve in KOH or HNO₃, but they yield a curious pinkish reaction in the former reagent. In the field, *L. destituta* is most likely to be confused with species of the *Buellia disciformis* (Fr.) Mudd group.

A thallus chemistry comprising atranorin only is unusual in Lecidella. In some Northern Hemisphere accounts (e.g. Poelt & Vězda 1981; Fletcher et al. 2009), L. euphorea (Flörke) Hertel is alluded to as being a xanthone-deficient relative of L. elaeochroma. Initially we entertained the notion that this could be an appropriate name for our Australian collections. However, every herbarium specimen labelled as L. euphorea that we were able to study (from Europe and North America) invariably contained xanthones (when examined by h.p.l.c). Furthermore, in their account of Sonoran species, Knoph and Leuckert (2004) consider L. euphorea as containing either atranorin only or atranorin plus xanthones. In their concept, the species also lacks an inspersed hymenium. Another species examined was the European L. achristotera (Nyl.) Hertel & Leuckert. This species is very similar to L. destituta in that it has the same apothecial pigmentation, ± identicalsized ascospores and, most importantly, an inspersed hymenium; however, it differs by containing xanthones (Nimis & Poelt 1987), including 2,5,7-trichloro-3-Omethylnorlichexanthone (our analyses). Similarly the saxicolous L. patavina (A. Massal.) Knoph & Leuckert also has an inspersed hymenium but differs chemically by containing atranorin and lichexanthone (Fletcher et al. 2009). Hence we concluded that the best outcome was to describe a new species.

Distribution and ecology: Lecidella destituta is an infrequently collected but almost certainly frequently overlooked species. It has been recorded from west of the Great Dividing Range in New South Wales, southwestern Western Australia and from Kangaroo Island, South Australia. In Tasmania, herbarium collections

suggest it is quite rare, ranging from lowland to subalpine altitudes and colonising twigs and small branches of shrubs and young trees in open eucalypt-dominated woodland. Associated species include *Buellia dissa* (Stirt.) Zahlbr., *Caloplaca wilsonii* S.Y.Kondr. & Kärnefelt, *Menegazzia subpertusa* P. James & D.J. Galloway, *Pertusaria pertractata* Stirt., *Usnea inermis* Motyka and various crustose lichens.

2. Lecidella elaeochroma (Ach.) Hazsl.

Magy Birod. Zuzmo-Flor.: 197 (1884); Lecidea parasema β elaeochroma Ach., Methodus: 35: (1803).

Thallus smooth, rimose-areolate to papillate, pale grey to cream-grey, often rather discontinuous and revealing a thin, blue-black prothallus beneath, esorediate, forming irregular, extensive, undelimited patches typically along twigs and small branches. Apothecia 0.2-0.8 mm wide, sessile, basally constricted; disc plane at first, later often becoming convex, typically black, but rarely also pale to dark brown or mottled, matt to glossy, epruinose. Proper excipulum black, glossy, mostly persistent but sometimes ± excluded in the most convex apothecia, entire, in section 20-50 µm thick, colourless to dilute reddish brown within, unchanged in K, N+ intensifying orange-brown, mostly with additional blue-green, N+ crimson pigment, especially at the upper and outer edges. Hypothecium 50-90 µm thick, pale yellowbrown to yellow-orange, intensifying yellow-orange in K and N. Hymenium 50-90 µm thick, separating easily in K, mostly not inspersed, in the upper part intensely to dilutely greenish blue, K ± grey-green, N+ crimson, towards the base mostly colourless, typically overlain by a layer of brownish granules to c. 5–10 µm thick that dissolve in K. Asci $40-60 \times 12-18 \,\mu\text{m}$. Paraphyses 1.5-2.5 μm thick, simple; apices usually expanded to 2–4 μm thick, mostly with an external, blue-green, N+ crimson cap but sometimes unpigmented. Ascospores broadly ellipsoid, $(9-)10-12.1-14(-15) \times (5-)5.5-6.4-7.5(-8) \mu m$. Conidiomata not observed. Fig. 1B

Chemical composition: As discussed by Knoph and Schmidt (1995) and Knoph and Leuckert (2004), this widespread species contains a complex range of xanthones. Material from mainland Australia and Tasmania revealed 2,5,7-trichloro-3-O-methylnorlichexanthone (major) together with arthothelin (±), isoarthothelin (±) atranorin (\pm) , 5,7-dichloro-3-O-methylnorlichexanthone (\pm) , 2,5-dichloronorlichexanthone (\pm) , 4,5-dichloronorlichexanthone (\pm) ,

2,4-dichloronorlichexanthone (±), 4,5-dichloro-3-O-

methylnorlichexanthone (±) and thuringone (±); thallus K-, KC-, C+ orange, P-, UV± weak orange.

Remarks: This distinctive species is recognised by the combination of the esorediate thallus containing xanthones, the presence of blue-green pigment in the excipulum and hymenium, the yellow-orange, K+intensifying hypothecium, the hymenium that is very lax in KOH, and the relatively small ascospores. Australian material concurs well with a wide a range of specimens from the Northern Hemisphere that were examined, as well as with published descriptions (Knoph & Leuckert 2004; Fletcher et al. 2009). However, unlike European specimens, the apices of the paraphyses of Australian specimens are almost always pigmented.

There are two additional species recognised in this account which have previously been included in a broad and very loosely defined concept of *Lecidella elaeochroma*. In drier, sclerophyll forests, there is *L. destituta*, which differs chiefly by containing atranorin only and having an inspersed hymenium. In highland areas of Tasmania, in habitats similar to those where *L. elaeochroma* might occur, there is *L. montana*, which differs by having larger ascospores and a persistent, opaque brown excipulum, and typically contains thiophanic acid and arthothelin.

Distribution and ecology: This very widespread, ± cosmopolitan species is very localised in Tasmania, where it is known from only a few collections, all from high, cold elevations, especially in relatively low-rainfall areas. Significantly, all specimens studied, even those from mainland Australia, grew on the twigs of the low, highly branched shrub, Hymenanthera dentata R.Br. ex DC. (Violaceae), where it forms a very extensive cover, colonising seemingly every centimetre of the small twigs and branchlets. Although in most cases it forms pure colonies, in one Tasmanian specimen it was associated with Teloschistes velifer F.Wilson, Ramalina glaucescens Kremp. and a tiny species of Caloplaca. In contrast, in the Northern Hemisphere, L. elaeochroma appears to be a widespread and broadly ecologically tolerant species found in woodland, heathland and on wayside trees.

Specimens examined: TASMANIA. Summit of Mount Wellington, 42°54′S 147°14′E, 1200 m alt., 9.i.1989, *M. Allen s.n.* (HO); Jacks Creek, 2 km NW of Lagoon of Islands, 42°04′S 146°54′E, 880 m alt., 27.ii.1984, *A. Moscal 6538 p.p.* (HO); Mt Ossa summit, 41°52′S 146°02′E, 1600 m alt., 14.iii.1992, *G.*

Kantvilas 442/92 & J.A. Elix (HO). AUSTRALIAN CAPITAL TERRITORY. Mt Clear, 35°53′S 158°05′E, 1590 m alt., 1.x.1980, H. Streimann 10589 (H. Hertel: Lecid. Exsicc. nr. 150) (HO).

3. *Lecidella flavovirens* Kantvilas & Elix, *sp. nov.* MycoBank No.: MB803600

Lecidellae xylogenae similis sed acidum thiophanicum continenti, sorediis primum in soraliis discretis, 0.2–0.5 mm latis enatis, excipulo atrofusco, pigmentum aeruginosum destituto et ascosporis grandioribus, 12–18 μm longis, 6–10 μm latis differt.

Type: TASMANIA. Ship Stern Bluff, 43°12'S 147°45'E, 80 m alt., on *Banksia marginata* in coastal scrub, 2 May 2011, *G. Kantvilas 185/11* (HO: holotype; BM, CANB: isotypes).

Thallus effuse, scurfy, pale grey, undelimited, lacking a prothallus, sorediate; soredia yellowish or greenish yellow, at first arising in discrete, roundish soralia c. 0.2-0.5 mm wide or, more rarely, irregularly in cracks in the thallus, soon spreading and coalescing, and the whole thallus becoming a rather thick, cracked sorediate mass, spreading in irregular, undelimited patches to 10 cm wide; soredia coarsely granular, with individual grains 20-30 µm wide. Apothecia 0.3-1 mm wide, sessile, basally constricted to rather adnate and nestling deeply amongst the soredia; disc plane or occasionally becoming convex, black, matt to glossy, epruinose. Proper excipulum concolorous with the disc, black, glossy, persistent, entire or occasionally flexuose, in section 30-60 µm thick, ± opaque dark brown, unchanged in K, N+ intensifying orange-brown, lacking blue-green pigments. Hypothecium 50-80 µm thick, colourless to pale yellow-brown, occasionally yellowish orange, more intensely coloured towards the base, intensifying yellow-orange in K and N. Hymenium 50-80 µm thick, in the upper part intensely to dilutely greenish blue, K± grey-green, N+ crimson, towards the base mostly colourless, not inspersed or overlain by granules, remaining rather coherent in K. Asci 45-55 × 15-24 μm. Paraphyses (1–)1.5 μm thick, simple; apices not markedly capitate, sometimes expanded to 2.5–4 μm, unpigmented or coated with blue-green, N+ crimson pigment. Ascospores (12–)13–15.2–17(–18) \times (6–)7–8.3–10 μm, broadly ellipsoid, sometimes a little apiculate at one or both apices. Conidiomata not observed. Fig. 1C

Chemical composition: thiophanic acid (major), 4,5-dichloronorlichexanthone (± minor), asemone (± minor), isoarthothelin (± trace), arthothelin (± trace), argopsin (± minor), 5,7-dichloronorlichexanthone (± trace), atranorin (± minor), norlichexanthone (±); thallus K-, C+ orange, KC-, P-, UV+ orange. The array of compounds, especially xanthones, can be quite complex but thiophanic acid is invariably present.

Remarks: This is a very distinctive species on account of its rather bright, eye-catching, yellowish to yellowish green sorediate thallus. It is commonly encountered as sterile thalli only, although fertile specimens are not infrequent. Whilst the nature and disposition of the apothecial pigmentation (blue-green in the hymenium, brown in the excipulum, yellow-brown in the hypothecium) is constant, their intensity is highly variable. Specimens from exposed microhabitats have very intensely pigmented apothecia, whereas those from shaded, moist sites can be very dilutely coloured.

Lecidella flavovirens has some superficial similarities to L. xylogena, which often has a similar, yellowish sorediate thallus. However, that species appears much finer, but this impression is due not to a difference in size of the soredia (these are ± the same in both taxa) but due to the soredia being very thick and agglomerated in L. flavovirens but rather thinly dispersed in L. xylogena. There are further, more fundamental differences between the two species. Unlike L. xylogena, L. flavovirens lacks blue-green pigment in the excipulum. In L. flavovirens, pigment occurs on the outside of the paraphyses (not as an internal cap), and it is probably due to this that they remain more conglutinated in KOH. The two species also differ in that L. xylogena has smaller ascospores and contains thiophaninic acid. Indeed L. flavovirens is probably most similar to the chiefly Northern Hemisphere taxon, L. scabra (Taylor) Hertel & Leuckert, which has a similar gross morphology, displays a similar disposition of apothecial pigments, has similarsized ascospores but differs chemically in containing atranorin and arthothelin (Knoph 1990), plus additional xanthones (our analyses).

Distribution and ecology: Lecidella flavovirens is a common and widespread species, recorded from Tasmania, Victoria, New South Wales, the Australian Capital Territory, South Australia (Kangaroo Island) and south-western Western Australia. In Tasmania, it is most commonly seen in coastal scrub and woodland, especially on Banksia marginata Cav., where it forms an extensive cover on trunks, young branches and twigs. It is also found in open, dry sclerophyll, eucalyptdominated communities where it colonises logs, the bases of eucalypts, and the bark of understorey trees such as Allocasuarina. In such habitats, it is commonly associated with Austroparmelina pseudorelicina (Jatta) A.Crespo et al., Flavoparmelia rutidota (Hook.f. & Taylor) Hale, Pertusaria pertractata Stirt., P. trimera (Müll.Arg.) A.W.Archer, Tephromela atra (Huds.) Hafellner, T. sorediata Kalb & Elix and Usnea inermis Motyka, as well as with its relative, L. xylogena. However, unlike that species, L. flavovirens has a broader ecological amplitude, extending into wet forests where it colonises understorey trees. In such habitats, associated lichens include Mycoblastus campbellianus (Nyl.) Zahlbr., M. coniophorus (Elix & A.W.Archer) Kantvilas & Elix and Thelotrema lepadimum (Ach.) Ach.

Selected specimens examined: TASMANIA. Coles Bay Conservation Area, 42°06'S 14B°15'E, S0 m alt., 17.vi.2007, G. 4. Lecidella granulosula (Nyl.) Knoph & Leuckert Herzogia 14: 9 (2000); Lecidea granulosula Nyl., in Cromb., J. Bot. 14: 21 (1876).

Thallus granular, continuous or in part dispersed, pale cream to yellowish grey, undelimited, lacking a prothallus, esorediate, forming patches to c. 10 cm wide. Apothecia 0.3-0.6 mm wide, sessile, basally constricted, scattered; disc persistently plane or becoming convex with age, black, matt, epruinose. Proper excipulum black, matt to glossy, entire, usually becoming rather obscure in the most convex apothecia, in section 25-40 µm thick, pale brown to brown within, intensifying in N, mostly together with blue-green, N+ crimson pigment that becomes more intense at the outer edge. Hypothecium 60-100 µm thick, colourless, becoming slightly yellowish in K. Hymenium 50-70 µm thick, separating easily in K, not inspersed, in the upper part dilutely to intensely blue-green, K± grey-green, N+ crimson, with or without epihymenial granules that dissolve in K. Asci $40-55 \times 12-18 \,\mu\text{m}$. Paraphyses 1-2 μm thick, simple or occasionally bifurcate near the apices; apices mostly expanded, with an external, blue-green, N+ crimson cap 3-5 µm wide. Ascospores broadly ellipsoid to rather oblong, $(9-)10-11.5-14 \times (4.5-)5-6.1-7(-8) \mu m$. Conidiomata not seen. Fig. 1D

Chemical composition: chodatin, demethylchodatin, thiophanic acid, 2,5,7-trichloro-3-O-methylnorlichexanthone (minor), thiophaninic acid (± minor), isoarthothelin (± minor), 2,4-dichloronorlichexanthone (± trace), 2,5,7-trichlorolichexanthone (± minor), 5,7-dichloro-3-O-methylnorlichexanthone (± trace), isoarthothelin (± minor); thallus K-, C+ orange, KC-, P-, UV+ orange.

Remarks: This species is readily recognised by the combination of the saxicolous habit, the finely granular thallus, the rather small apothecia and the colourless hypothecium (see also Knoph & Leuckert 2004). The morphology of the thallus can resemble that of Lecidella sublapicida, but that species has a yellow-brown to reddish brown hypothecium and differs chemically in containing vicanicin in addition to a suite of xanthones;

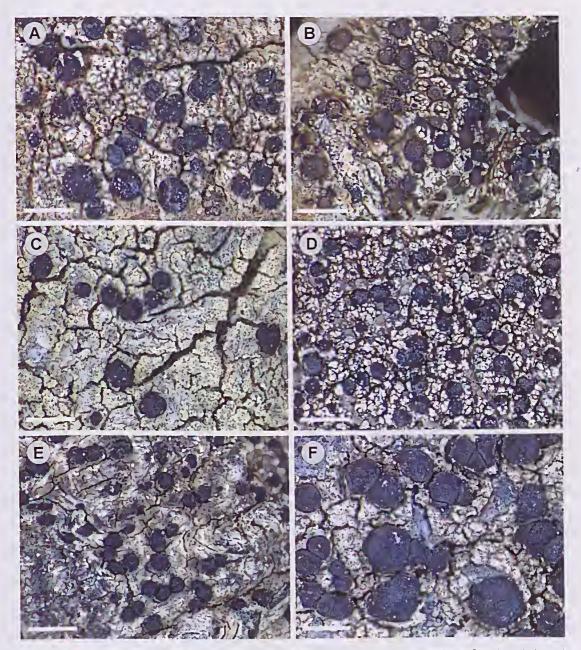

Figure 1. Habit of Lecidella species. A. L. destituta (holotype); B. L. elaeochroma (Kantvilas 116/92); C. L. flavovirens (holotype); D. L. granulosula (Elix 28764 & Kantvilas); E. L. montana (Kantvilas 142/00); F. L. stigmatea (Kantvilas 168/98). Scale = 1 mm.

Muelleria 39

furthermore the thallus of *L. sublapicida*, although often rather granular and warty, is much coarser. Of the species studied, *L. stigmatea* is the only other saxicolous species that has a colourless hypothecium, but it differs from *L. granulosula* by having much larger apothecia, a thicker thallus containing atranorin and zeorin, and a predominantly brown to purple-brown epihymenium.

Distribution and ecology: This species is widespread in both hemispheres and in Australia has previously been recorded from New South Wales (Knoph 1990; Knoph & Leuckert 2000) and Tasmania (Elix 2006). It appears to be quite uncommon (or overlooked). In Tasmania, it was recorded from rocks in rough pasture in a very low rainfall (c. 500 mm per annum) area, where it was associated with species of Xanthoparmelia, Acarospora and other crustose lichens. On Kangaroo Island, it was collected from eutrophicated coastal rocks in a penguin colony.

Specimens examined: TASMANIA. Lower Marshes Road, c. 1 km SW of Northumbria Hill, 42°23′S 147°15′E, 450 m alt., 9.xi.2004, J.A. Elix 28764 & G. Kantvilas (HO); Clarke Island, 40°30′S 148°10′E, 186 m alt., 1.iv.1980, J.S. Whinray 1466 (HO, MEL). NEW SOUTH WALES. Goonoo State Forest, Cashels Dam Road, 31 km SE of Gilgandra, 31°55′57″S 148°52′17″E, 390 m alt., 12.x.2005, J.A. Elix 37979 (CANB); Gibraltar Range State Forest, 49 km E of Glen Innes, 29°36′17″S 152°10′34″E, 1020 m alt., 2.v.2005, J.A. Elix 39406 (CANB). SOUTH AUSTRALIA. KANGAROO ISLAND, Northern end of Antechamber Bay, 35°47′S 138°04′E, 5 m alt., 19.ix.2011, G. Kantvilas 399/11 (HO).

5. *Lecidella montana* Kantvilas & Elix, *sp. nov.* MycoBank No.: MB803598

Lecidellae elaeochromae commonita sed hymenio potius cohaerenti, ascosporis magnioribus, 15–24 μm longis, 8–13 μm latis, et acidum thiophanicum continenti differt.

Type: AUSTRALIA, TASMANIA. Falling Mountain, 41°55′S 146°06′E, 1480 m alt., on twigs of *Diselma archeri* in alpine heathland, 11 March 2011, *G. Kantvilas 137/11* (holotype: HO).

Thallus mostly rather patchy and discontinuous, revealing a thin blue-black prothallus beneath, effuse, smooth to rimose-areolate, rarely a little papillate, pale yellowish grey to cream-grey, esorediate, forming irregular, undelimited patches, sometimes to 10 cm wide

but typically much smaller. Apothecia 0.2-0.7 mm wide, sessile, basally constricted; disc plane or occasionally becoming convex, black, matt to glossy, very rarely brown to dark brown, epruinose. Proper excipulum black, glossy, persistent, entire or occasionally flexuose or crenulate, in section 30-50 μm thick, pale to opaque dark brown within, unchanged in K, N+ intensifying orange-brown, sometimes also with blue-green, N+ crimson pigment at the inner edge. Hypothecium 30-100 µm thick, pale yellow-brown to yellow-orange, more intensely coloured towards the base, intensifying yellow-orange in K and N. Hymenium 70-100 μm thick, not inspersed, remaining rather coherent in K, in the upper part intensely to dilutely greenish blue, K± greygreen, N+ crimson, towards the base mostly colourless, commonly overlain by a layer of brownish granules to c. 10 μ m thick that dissolve in K. Asci 55–70 \times 18–30 μ m. Paraphyses 1.5-2 µm thick, simple or with occasional branches and anastomoses; apices usually expanded to 2.5-5 µm thick, usually coated with blue-green, N+ crimson pigment. Ascospores 15-18.1-22(-24) × 8-10.3-12(-13) µm, broadly ellipsoid, frequently discoloured pale olive-brown. Conidiomata not observed. Fig. 1E

Chemical composition: thiophanic acid (major), isoarthothelin (\pm minor), 2,5,7-trichloro-3-*O*-methylnorlichexanthone (\pm), asemone (\pm trace); thallus K-, C+ orange, KC-, P-, UV+ orange.

Remarks: With its abundant black apothecia, pale yellowish-tinged, xanthone-containing thallus and predominantly twig habitat, this species is superficially similar to Lecidella elaeochroma. Like that species, it also has a K+ yellow-orange intensifying hypothecium and a granular epihymenium. It differs chiefly by its incrementally larger ascospores: in L. elaeochroma these are not known to exceed 17 µm in length, whereas in L. montana they are seldom shorter than that. Additional distinguishing features of L. montana include the relatively coherent hymenium in KOH, and the excipulum which is typically opaque brown in section and largely lacks blue-green pigment. Furthermore, the excipulum in the new species tends to be persistent, whereas in L. elaeochroma it is eventually excluded as the apothecia become very convex. The intensity of apothecial pigmentation appears to be linked to the degree of exposure. In extreme shade, such as within a dense shrub, the apothecia can have a brownish disc. In exposed habitats, the apothecia are jet black,

and the blue-green pigment saturates the hymenium and clothes the upper parts of the paraphyses. The thallus varies from being almost absent, to consisting of rather dispersed, pale areoles, to being darker and \pm continuous; again this variation is attributed to habitat factors.

The generic placement of this new species remains somewhat uncertain. The combination of its gross morphology, general pigmentation of the apothecia, structure of the excipulum and thallus chemistry are all consistent with *Lecidella*. However, the coherent hymenium is not, and the asci, although mostly of the *Lecidella*-type, may also tend towards the *Lecanora*-type, where the *masse axial*e penetrates the tholus \pm entirely. However, at this point, there appears to be no better taxonomic placement for this lichen. The genus *Carbonea* was considered, but to place this epiphytic species into an essentially saxicolous genus seems inappropriate.

Distribution and ecology: This species is common and widespread in highland areas in Tasmania, where it is found on living and dead twigs and small branches of various trees and shrubs in heathland and woodland, for example, species of Orites R.Br., Microstrobos niphophilus J.Garden & L.Johnson, Diselma archeri Hook.f., Nothofagus cunninghamii (Hook.) Oersted and Epacris serpyllifolia R.Br. It is commonly the dominant lichen in such habitats, clothing the entire length of the substrate and consequently occurs in pure colonies rather than in association with other lichens. It also colonises the fibrous bark of the trunks of the conifer Athrotaxis cupressoides D.Don. It is typically quite conspicuous, with its abundant black apothecia contrasting with the pale colour of the bleached twigs on which it grows.

Specimens examined: TASMANIA. Lake Skinner, 42°S6′S 146°41′E, 970 m alt., 17.v.2008, G. Kantvilas 200/08 (HO); summit of Rodway Range, 42°41′S 146°34′E, 1375 m alt., 17.iv.2006, G. 6. Lecidella stigmatea (Ach.) Hertel & Leuckert

Willdenowia 5: 375 (1969); Lecidea stigmatea Ach., Lich. Univ.: 161 (1810).

Thallus rimose-areolate to rather lumpy and verruculose, continuous or dispersed, pale cream- to grey-brown, sometimes discoloured brownish, undelimited, lacking a prothallus, esorediate, forming extensive patches to c. 20-30 cm wide. Apothecia 0.4-1.5 mm wide, sessile, basally constricted, scattered or crowded together; disc plane, becoming undulate to convex in the oldest, largest apothecia, black, matt, epruinose. Proper excipulum black, matt to glossy, mostly persistent although occasionally rather obscure in the most convex apothecia, entire, in section 35-50(-80) µm thick, blue-green, K± grey-green, N+ crimson at the outer edge, increasingly dilute blue-green to colourless within. Hypothecium 60-150 µm thick, colourless or occasionally pale yellow-brown at the base. Hymenium 60–100 µm thick, separating easily in K, not inspersed, in the upper part brownish to purple-brown, intensifying in K, typically also with at least some blue-green, N+ crimson pigment, towards the base mostly colourless, not overlain by epihymenial granules. Asci 45-60 imes 13-20 μ m. Paraphyses 1-2 μ m thick, simple; apices unpigmented and not expanded or, more commonly, with an external, blue-green, N+ crimson cap 2.5-5 μm wide. As cospores broadly ellipsoid to rather oblong, (10-) 11–13.4–15(–16) \times (6–)6.5–7.8–9(–10) μ m. Conidiomata rare, located in only one specimen, immersed; conidia thread-like, curved, c. $12-20 \times 1 \mu m$. Fig. 1F

Chemical composition: atranorin and zeorin; thallus K+ weakly yellow, KC-, C-, P-, UV-.

Remarks: This species is characterised by the relatively wide-spreading, well-developed thallus containing atranorin and zeorin (an unusual chemistry for the genus), the relatively large apothecia that become convex at maturity, and the often-massive, mainly colourless hypothecium (see also Knoph & Leuckert 2004; Fletcher et al. 2009). Of the saxicolous

species studied, *Lecidella stigmatea* shares a colourless hypothecium with *L. granulosula*, but that species differs by its granular thallus containing xanthones (C+ orange) and by its smaller apothecia. It differs starkly from *L. sublapicida*, which has a brownish hypothecium and also contains xanthones.

Distribution and ecology: Lecidella stigmatea is a very widespread species in both hemispheres, occurring mainly on calcareous substrates. Its Tasmanian distribution ranges from limestone outcrops in natural vegetation to concrete in a suburban garden. Several collections are also from dolerite, a siliceous rock type, in sites subject to nutrient enrichment, such as boulders in rough sheep-grazing land. Associated species include Lecanora dispersa (Pers.) Sommerf., Candelariella aurella (Hoffm.) Zahlbr., C. vitellina (Hoffm.) Müll.Arg. and species of Caloplaca. It was first reported for Tasmania by Hertel (1989).

Specimens examined: TASMANIA. Lune River Lagoon mouth, 43°26′S 146°55′E, 1968, G.C. Bratt 68/523 (HO); Glen Morey Saltpan near Tunbridge, 42°09′S 147°29′E, 175 m alt., 1984, A. Moscal 8793 (HO); Giblin River, c. 7 km SW of Hardwood Hill, 70 m alt., 1985, G. Kantvilas 182/85 (HO); Cascades, Hobart, 42°54′S 147°17′E, 130 m alt., 1998, G. Kantvilas 168/98 (HO); Bisdee Tier, 42°26′S 147°17′E, 640 m alt., 2009, G. Kantvilas 171/09 (HO). AUSTRALIAN CAPITAL TERRITORY. Brindabella Range, summit of Mt Aggie, 35°28′S 148°46′E, 22.xi.1989, W.H. Ewers 4610 (CANB).

7. Lecidella sublapicida (C. Knight) Hertel

Mitt. Bot. München 19: 444 (1983); Lecidea sublapicida C. Knight, *Trans. N.Z. Inst.* 8: 316 (1876).

Thallus rimose-areolate to rather granular-verruculose, continuous or dispersed, pale pinkish brown, creamgrey to grey-brown, undelimited, sometimes very thin to absent, lacking a prothallus, esorediate, forming irregular patches to c. 10 cm wide. Apothecia 0.2–0.8 mm wide, scattered or crowded together, sessile, basally constricted; disc mostly persistently plane, sometimes a little undulate but only rarely convex, black, matt to glossy, epruinose. Proper excipulum black, matt to glossy, entire to a little flexuose, mostly persistent or becoming inconspicuous and excluded, especially in more convex apothecia, in section 15–50 µm thick, opaque red-brown within, unchanged in K, N+ intensifying orange-

brown, also with additional blue-green, N+ crimson pigment, particularly at the edges, rarely ± entirely deep blue-green. Hypothecium 20-100 µm thick, yellowbrown to deep brown, intensifying yellow-orange in k and N, typically subtended by a darker red-brown layer continuous with the excipulum. Hymenium 55-90 μm thick, separating easily in K, in the upper part intensely greenish blue, K±grey-green to blue-green, N+ crimson, towards the base mostly colourless, occasionally overlain by brownish granules that dissolve in K. Asci $40-60 \times 12-20 \mu m$. Paraphyses 1-2 μm thick, simple to sparsely branched; apices unpigmented and only slightly expanded to 2-2.5 µm wide or, more commonly, with an external, blue-green, N+ crimson cap 2-4 μm wide. Ascospores broadly ellipsoid to ovate, (9-)10- $12.3-15(-17) \times (4.5-)6-6.9-8(-9) \mu m.$ Conidiomata not observed. Fig. 2A

Chemical composition: vicanicin, 2,5,7-trichloro-3-O-methylnorlichexanthone, 5,7-dichloro-3-0 methylnorlichexanthone, isoarthothelin (minor). arthothelin (± minor), atranorin (± minor), vicanicin methyl ether (± minor), 5,7-dichlorolichexanthone minor), 3-O-methylasemone (± 3-O-methylthiophanic acid (± minor), thiophanic acid (± minor), 2,5,7-trichlorolichexanthone (± minor); thallus K-, KC-, C+ orange, P-. The suite of xanthones present is highly variable and not easily detected by thin-layer chromatography; however, vicanicin is inevitably present. In specimens where the thallus is extremely thin to absent, thin-layer chromatography may not detect any substances.

Remarks: Lecidella sublapicida is recognised by its often rather granular thallus, and abundant, black, usually persistently marginate apothecia with a redbrown to yellow-brown hypothecium. Unlike in most other Lecidella species studied, the excipulum appears to be cupular or almost so, and extends continuously beneath the hymenial and subhypothecial layers, forming a secondary, deeper brown layer of tissue. Also characteristic is the presence of vicanicin together with a suite of xanthones. The dark hypothecium is unique to Lecidella in Tasmania and the presence of vicanicin is diagnostic.

This species is very closely related to the widespread, chiefly Northern Hemisphere taxon, *L. carpathica* Körb., which has an identical habitat ecology, a

virtually identical thallus morphology and apothecial anatomy, but differs chemically in containing diploicin (instead of vicanicin) and the xanthone thuringione (see also Knoph 1990). This subtle chemical difference requires high performance liquid chromatography for accurate determination. Although *L. carpathica* has been recorded for Tasmania, it appears to have been consistently mistaken for *L. sublapicida*, and all material studied has been determined by us as the latter.

Another anatomically similar species with a yellow-brown hypothecium and a granular-verrucose thallus containing xanthones is *L. wulfenii* (Hepp) Körb., which is widespread in the Northern Hemisphere where it grows over bryophytes and soil (Knoph & Leuckert 2004; Fletcher et al. 2009). It has also been recorded occasionally in the Southern Hemisphere: from New Zealand (Galloway 2007) and the Subantarctic islands (Øvstedal & Lewis Smith 2001). We originally contemplated including one unusual Tasmanian specimen (*Kantvilas 923/01*), collected from alpine bryophytes overgrowing a boulder, as this species. However, in addition to a suite of xanthones, this specimen also contains vicanicin, an unusual and diagnostic substance in *Lecidella*, and hence we have determined it as *L. sublapicida*.

Distribution and ecology: This is a very widespread, saxicolous species in the temperate Southern Hemisphere. In Tasmania, it displays a very wide ecological amplitude, ranging from the coast to the summits of the highest peaks. It is often found in nutrient-enriched habitats. For example, at alpine elevations it grows on large, bird-perch boulders where it is part of a rich lichen community that includes Xanthoria candelaria (L.) Th.Fr., Candelariella vitellina (Hoffm.) Müll.Arg., Protoparmelia badia (Hoffm.) Hafellner, Xanthoparmelia loxodella (Essl.) O.Blanco et al., Immersaria athroocarpa (Ach.) Rambold & Pietschm. Rimularia psephota (Tuck.) Hertel & Rambold, Usnea torulosa (Müll.Arg.) Zahlbr., Lecanora polytropa (Ehrh.) Rabenh. and L. rupicola (L.) Zahlbr. It has also been recorded in areas of human-induced eutrophication, such as on rocks splashed by urine in the vicinity of bush-walkers huts. In such habitats, it may form extensive, pure colonies. In rough grazing land it occurs on boulders amongst grasses. On coastal rocks it can be found associated with species of Xanthoparmelia and Caloplaca. Although exclusively saxicolous, one specimen studied was from hardened gloss house paint. The unusual muscicolous specimen was from the moist, sheltered face of a large dolerite boulder in highland eucalypt woodland, where it was associated with *Teloschistes spinosus* (Hook.f. & Taylor) J.S.Murray, the basal squamules of *Cladonia* and incipient thalli of Parmeliaceae.

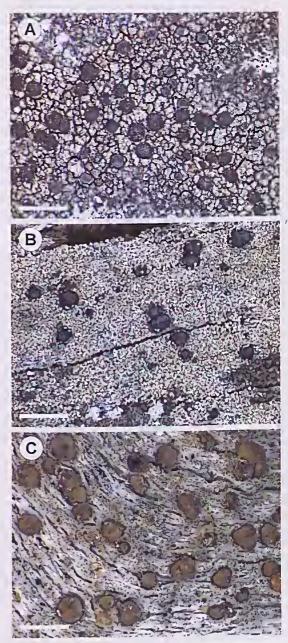

Figure 2. Habit of Lecidella species. A. L. sublapicida (Kantvilas 570/00); B. L. xylogena with typical, farinose sorediate thallus and dark-pigmented apothecia (Bastow s.n.); C. L. xylogena with highly reduced, esorediate thallus and pallid apothecia (Kantvilas 303/05). Scale = 1 mm.

Specimens examined: TASMANIA. Mt King William I, 42°14'S 146°08'E, 1240 m alt., 31.i.1984, G. Kantvilas 88/84B (HO); Couta Rocks, 41°10'S 144°41'E, 9.xii.1993, G. Kantvilas 304/93 & J. 8. Lecidella xylogena (Müll. Arg.) Kantvilas & Elix, comb. nov.

MycoBank No.: MB803601

Lecidea xylogena Müll. Arg., Bull. Herb. Boissier 1: 44 (1893).

Type: VICTORIA. On dead wood, 1892, F.R.M. Wilson 1339 (holotype: GI; isotype: BM!).

Thallus scurfy or rarely composed of minute, dispersed areoles, sometimes \pm absent or inapparent, pale grey to yellowish, occasionally \pm esorediate, but more commonly soon dissolving \pm entirely into a conspicuous, pale yellowish to greenish yellow sorediate mass, spreading in irregular, undelimited patches c. 10–30

mm wide; soredia farinose to coarsely granular, with individual grains 16-30 µm wide. Apothecia 0.3-0.7 mm wide, sessile, basally constricted to rather adnate, often nestling deeply amongst the soredia; disc plane to slightly concave, pale brownish to brown-grey, rarely dark grey to brownish black, rather waxy, typically epruinose but rarely with a thin, discontinuous, greyish pruina. Proper excipulum dark grey to black, more rarely pale to dark red-brown, rather glossy, persistent, entire or occasionally flexuose, in section 15-40 µm thick, grey-green to pale brownish within, usually more intensely pigmented greenish blue, N+ crimson towards the outer edge, more rarely entirely lacking pigment. Hypothecium 40-120 µm thick, colourless to pale brownish, unchanged or intensifying brownish yellow in K. Hymenium 50-70 µm thick, colourless, not inspersed, very lax and separating readily in K, overlain by an epithecium c. 10 µm thick consisting of brownish granules that dissolve in K and the grey-green apices of the paraphyses. Asci 40-55 × 13-20 µm. Paraphyses (1-)1.5(-2) µm thick, simple except for occasional bifurcations at the apices, markedly capitate; apices 3.5-5 µm wide, occasionally a little moniliform, with an internal cap of grey-green, N+ crimson pigment. Ascospores $(7-)8-10.9-14 \times 4-6.3-8(-9) \mu m$, broadly ellipsoid. Conidiomata not observed. Figs 2B-C

Chemical composition: thiophaninic acid (major), thiophanic acid (± trace), 2,4-dichloronorlichexanthone (± trace), 2,5,7-trichloro-3-O-methylnorlichexanthone (±), asemone (± trace), isoarthothelin (± trace), isopigmentosin B (± trace), isopigmentosin C (± trace), usnic acid (± trace); thallus K-, C+ orange, KC-, P-, UV+ orange. The chemical composition of this species can be rather variable. Thiophaninic acid is the major compound in the great majority of specimens studied, including the type. Occasional specimens yielded no chemistry, but this is attributed to having attempted to extract too little thallus material. Two enigmatic specimens (Kantvilas 131/06, 235/09) lack thiophaninic acid but contain arthothelin as the major compound, whereas a third (Ratkowsky s.n., HO 301660) contains 2,5,7-trichloro-3-O-methylnorlichexanthone. Nevertheless, all display the distinctive and highly characteristic anatomical features of thiophaninic acidcontaining specimens (see discussion below).

Remarks: This is a variable species morphologically and anatomically. The type specimen of Lecidella

xylogena has a yellowish, finely farinose sorediate thallus containing thiophaninic acid, relatively small apothecia with a pale disc and darker, thin persistent margin, a granular, brownish epithecium that dissolves in KOH, capitate, apically pigmented paraphyses that are very lax in KOH, and rather small ascospores. The majority of specimens studied display these features. The paraphyses in particular are highly distinctive: whereas in all the other species studied, any apical pigmentation occurs as an external cap, in L. xylogena, the pigmentation is entirely within the markedly expanded terminal cell. The soredia in L. xylogena do not arise from discrete soralia but are derived from a general disintegration of the thin, scurfy thallus. In some specimens, the thallus is ± absent whereas in others, soredia are barely developed and the thallus consists of tiny yellowish granules; in these instances, the anatomy of the apothecia determine the identity of the specimens. Very occasional specimens (or parts of specimens) have entirely pale to dark reddish brown apothecia that lack almost any trace of blue-green pigment; this is attributed to the degree of exposure of the microhabitat.

In exploring the chemical variation of this species. we looked for correlations between chemistry and anatomical/morphological characters but without success, and the more specimens or apothecial sections were examined, the more any suspected correlations, for example with ascospore size, became blurred. Specimens containing 2,S,7-trichloro-3-Omethylnorlichexanthone (instead of thiophaninic acid) were especially problematic. For these the name Lecidea leptolomoides Müll.Arg (syn. L. minutula Müll.Arg) could be available. The isotypes of these two taxa (in NSW) both have this chemistry and represent a Lecidella with a very thin, inconspicuous, esorediate thallus, collected from the bark of exotic trees in Victoria. Yet anatomically both specimens display all the key characters of L. xylogena with respect to ascospore size, paraphyses and excipular pigmentation. At this stage we are reluctant to formally synonymise these names, but we are nevertheless placing all specimens with the characters outlined above under the name L. xylogena regardless of thallus chemistry.

The most similar species to *L. xylogena* is *L. flavovirens*, which differs by having a much coarser, thicker,

sorediate thallus in which the soredia initially arise in discrete soralia and then spread and coalesce, and has more intensely pigmented apothecia in which there is no brown, granular epithecium, and in which the blue-green pigment is confined to the upper part of the hymenium (and does not occur in the excipulum). Lecidella flavovirens differs further by having larger ascospores and by containing thiophanic acid as the major compound. Also somewhat similar is the Northern Hemisphere's *L. subviridis* Tønsberg, but this contains atranorin in addition to thiophanic acid and arthothelin (our analyses), and has larger ascospores (Fletcher et al. 2009).

Lecidella xylogena can also rarely be confused with Ramboldia sorediata Kalb in that both can have an entirely sorediate thallus and occur in the same habitats. The latter species typically has a whitish thallus, but it can occasionally become a little yellowish green. Such specimens are readily identified as Ramboldia by their chemistry (thamnolic acid, K+ yellow). Also similar is a rather common, yellowish, entirely sorediate, sterile lichen that occurs on old worked timber in gardens; it contains usnic acid as the major compound and is likely to be a species of Lecanora.

Distribution and ecology: Lecidella xylogena is a tiny species found mainly on the lignin or bark of eucalypts or on understorey trees such as Allocasuarina in dry sclerophyll woodlands, especially at low elevations. There it is part of a rich association of small, mainly lignicolous lichens, including Buellia spp., Candelariella reflexa (Nyl.) Lettau, Lecanora subtecta (Stirt.) Kantvilas & LaGreca, Micarea spp., Pertusaria pertractata Stirt., Punctelia pseudocoralloidea (Gyel.) Elix & Kantvilas, Ramboldia sorediata Kalb, Rinodina asperata (Shirley) Kantvilas and Usnea inermis Motyka. It has also been collected from split eucalypt fence posts in pasture land and from the bark of exotic trees such as Prunus species in cultivated gardens. Less commonly it occurs at alpine elevations on eucalypt wood and on the twigs of shrubs such as Richea sprengelioides (R.Br.) F. Muell. It has been recorded in eastern and northern Tasmania, Victoria, Kangaroo Island (South Australia) and the Australian Capital Territory, but can be expected to be widespread in low rainfall areas of southern Australia.

Selected specimens examined: TASMANIA. Launceston, Carr Villa Cemetery, 41°28'S 147°10'E, 80 m alt., 4.ii.1992, A.V.
